\textbf{ABSTRACT}

\textbf{Introduction}: Au(III) complexes with dithiolene ligands have been used as molecular conductors and magnetic materials [1]. These compounds feature square planar geometries, as that for cisplatin the Pt(II)-based compound in clinical use as chemotherapeutic drug. Based on the molecular structure, a similar mechanism of action, e.g. antitumor activity and
interaction with DNA should be expected for these compounds. Reports on the biological activity of similar gold(III) compounds are relatively scarce in the literature. Only recently, a Au(III) 1,2-dithiolene cyclometalated complex had proved its potential against Gram-positive bacteria [2]. In this study we evaluated two related Au(III) complexes containing N-alkyl-1,3-thiazoline-2-thione dithiolate ligand, [Au{(R-thiazdt)}₂]^− (R = ethyl-1; R = hydroxyethyl-2) [3a,b] as antitumor and antimicrobial agents. The compounds were assessed in vitro towards cisplatin sensitive ovarian cancer cells (A2780), bacteria and fungus of clinical importance such as Staphylococcus aureus and Candida. Spectroscopic studies were also performed to evaluate the interaction with DNA.

Materials and methods: The gold complexes were synthesised as previously described [3a,b]. The cytotoxic activity against the A2780 ovarian cancer cells was assessed by the IC₅₀ determined by the MTT assay. The antimicrobial activities of complexes 1 and 2 were assayed by the MIC values towards the Gram + S. aureus, and the fungal strains C. glabrata and C. albicans, using reported methods [4,5]. The ability of compounds to bind to DNA was assessed by fluorescence spectroscopy using ethidium bromide (EB) as the fluorescence probe.

Results: Complexes 1 and 2 presented high cytotoxic activity in the cisplatin sensitive A2780 cells even superior than cisplatin. Complex 1 was able to inhibit the growth of S. aureus and both Candida strains, while 2 was much less active. The fluorescence studies revealed a weak interaction of compounds with CT-DNA, in contrast with that found for cisplatin, although the interaction of 2 is somewhat stronger than that found for 1.

Discussion and conclusions: Results evidenced the importance in what way minor modifications of the Au dithiolate structure can result in loss of activity in particular the antimicrobial activity. In contrast with cisplatin, DNA is not the main target involved in their mode of action. Further studies are needed to explore other potential targets and the mechanism of action.

ABSTRACT

Introduction: The acute toxicity of cyanide along with its continue industrial use makes this substance of environmental concern [1]. Titration, spectrophotometry and ISE are the standard detection methods. However, they are complex and need sample pre-treatment [2]. To overcome these, another approach is using biosensors. To this end, we developed a disposable inhibition-based biosensor with a multi-heme nitrite reductase (ccNiR) coupled to graphite leads.
